0. Get a canvas

Two cards make a canvas and paint it. **createCanvas** takes two numbers: the width and the height, in pixels. **background** takes one colour card.

Everything in **setup** goes in a column under the **define setup** card.

Lay the cards like this

The outlines are already in the coding space on the table: lay each card over its outline.

> **You should see:** a blue square in the canvas space.

Try these

- Make the canvas a different shape. Try 500 and 200, then 200 and 500. Which of the two numbers is the width?
- Swap the **mediumblue** card for a different colour card.
- Take the **background** row off the table and watch the canvas. Put it back.

What just happened

A card like **createCanvas calls a function**: it runs a named piece of behaviour that somebody else wrote. The cards to its right are its **arguments**, the information the function needs to do its job.

50 mm: check the print scale

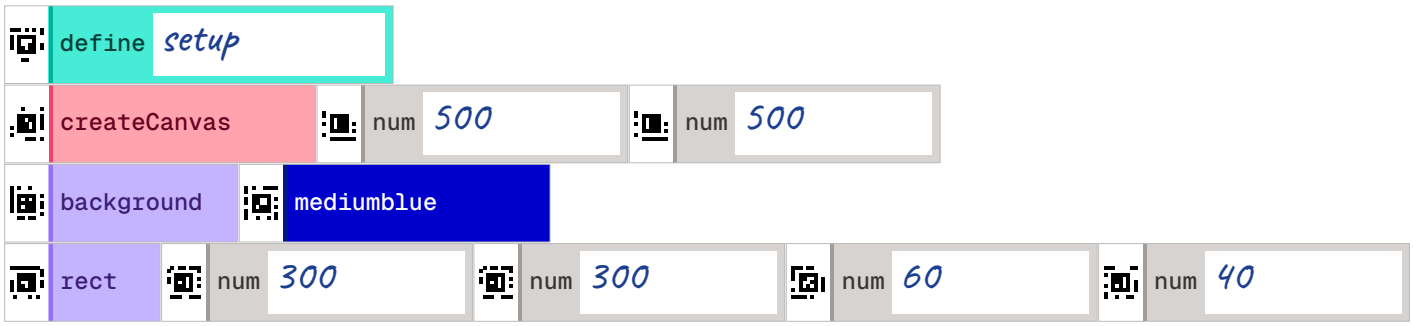

1. Put something on it

rect draws a rectangle. It takes four numbers, and the order they sit in tells the function which is which: `rect x y width height`.

x is how far across from the left edge. **y** is how far **down** from the top edge: a bigger y is lower, not higher. The x and y are the rectangle's **top-left corner**, not its middle.

Lay the cards like this

The outlines are already in the coding space on the table: lay each card over its outline.

> **You should see:** a small white rectangle, below and to the right of the middle.

Try these

- Change the first two numbers of **rect** to 0 and 0. Where does it go?
- Change them to 250 and 250. Is the rectangle in the middle? If not, why not?
- Build a **second** rect row under the first, with different numbers.

Before you turn the page

Make sure everyone at the table can put a finger on the card that decides how far **down** a rectangle sits.
